Code Overview: Library and Module Imports

This section imports all the core libraries, models, and dataset utilities required for evaluating the garbage classification models. Each import plays a specific role in loading data, running inference, computing metrics, and visualizing results.

Core Libraries

- **torch** — Runs the trained PyTorch models and handles tensors during inference.
- **numpy** — Supports numerical operations and array manipulation.
- **random** — Used for sampling random incorrect predictions for visualization.

Visualization Tools

- **matplotlib.pyplot** — Displays images, plots, and visual summaries.
- **seaborn** — Creates heatmaps for confusion matrices and other styled visualizations.

Evaluation Metrics

Imported from `sklearn.metrics`:

- **accuracy_score** — Measures overall correctness of predictions.
- **precision_score, recall_score, f1_score** — Provide deeper insight into per-class performance.
- **classification_report** — Summarizes precision, recall, and F1 for all classes.
- **confusion_matrix** — Shows how predictions are distributed across true classes.

Dataset and Data Loading

- **GarbageDataset, collate_fn** — Custom dataset and batching logic for loading images and text.
- **DataLoader** — Efficiently batches and loads test samples for evaluation.
- **transforms (torchvision)** — Applies preprocessing steps such as resizing and normalization.

Model Architectures

These are the four models being compared:

- **ImageOnlyModel** — Baseline model using only image features.
- **ResNetTextModel** — Multimodal model combining ResNet image features with text embeddings.
- **ResNetLSTMModel** — Multimodal model using ResNet for images and an LSTM for text encoding.
- **EfficientNetTextModel** — Best-performing multimodal model using EfficientNet for image features.

Device Setup Explanation

This section detects whether a GPU is available and configures PyTorch to use the most powerful device for model evaluation. Using a GPU significantly accelerates inference, especially for deep neural networks such as EfficientNet, ResNet, and multimodal architectures.

- `torch.device(...)` selects **CUDA** if a GPU is available; otherwise it falls back to **CPU**.
- The script prints the active device so the user can verify whether evaluation is running on GPU or CPU.
- When a GPU is present, `torch.cuda.get_device_name(0)` displays the specific GPU model (e.g., NVIDIA A100, RTX 3090), which is useful for debugging performance or documenting the hardware used in experiments.

This setup ensures that all subsequent model loading and inference operations automatically run on the correct device.

In [2]:
```python
# ========================
# DEVICE SETUP
# ========================

device = torch.device("cuda" if torch.cuda.is_available() else "cpu")

print("Using device:", device)

if torch.cuda.is_available():
    print("GPU:", torch.cuda.get_device_name(0))
```

```
Using device: cuda
GPU: Tesla T4
```

Dataset and Model Path Configuration

This section defines all file system paths required for loading the dataset and the trained model checkpoints used in evaluation. Centralizing these paths makes the evaluation script easier to maintain, modify, and reuse.

Dataset Paths

- **`train_path`** — Location of the training dataset used during model development.
- **`test_path`** — Location of the test dataset used for final evaluation and comparison across models.
  These paths point to the pre-split dataset provided for the assignment.

Model Checkpoint Paths

Each trained model is saved as a `.pth` file and loaded during evaluation:

- **`model_path_image_only`** — Checkpoint for the baseline model using only image features.
- **`model_path_resnet_weights`** — Checkpoint for the multimodal ResNet-Text model.
- **`model_path_resnet_lstm`** — Checkpoint for the ResNet + LSTM multimodal architecture.
- **`model_path_efficientnet`** — Checkpoint for the EfficientNet-Text model, the strongest performer.

These paths allow the notebook to load each model independently and run consistent evaluation across all architectures.

Purpose

Defining all paths in one place ensures:

- Easy switching between models
- Cleaner code organization
- Reduced risk of hard-coded or inconsistent paths
- Reproducibility of results across different machines or environments.

In [3]:
```python
# ========================
# PATHS
# ========================

train_path = "/home/aparna.ayyalasomayaj/garbage_data/CVPR_2024_dataset_Train"
test_path  = "/home/aparna.ayyalasomayaj/garbage_data/CVPR_2024_dataset_Test"

model_path_image_only = "/home/aparna.ayyalasomayaj/garbage_classification/image_only_model_final.pth"
model_path_resnet_weights = "/home/aparna.ayyalasomayaj/garbage_classification/resnet_text_model_final.pth"
model_path_resnet_lstm = "/home/aparna.ayyalasomayaj/garbage_classification/resnet_lstm_model_final.pth"
model_path_efficientnet = "/home/aparna.ayyalasomayaj/garbage_classification/efficientnet_text_model_final.pth"

print("Paths configured")
```

```
Paths configured
```

Image Transform Configuration

This section defines the preprocessing pipelines used for each model during evaluation. It is essential that these transforms **match the preprocessing used during training**, otherwise the model may receive inputs in a different format and produce incorrect predictions.

Why Transforms Matter

Neural networks are sensitive to:

- input resolution
- normalization statistics
- augmentation choices
- preprocessing order
  Using the same transforms as training ensures consistent feature distributions and stable evaluation performance.

Transforms Used

1. General Transform (128×128)

Used for lightweight CNNs and the Image-Only model.

- Resizes images to **128×128**
- Converts to tensor
- Normalizes using **ImageNet mean and std**

2. Image-Only Model Transform

Identical to the general transform above.

- Ensures the baseline model receives the same preprocessing as during training.

3. ResNet-Based Models Transform (224×224)

ResNet architectures expect **224×224** inputs.

- Resizes to 224×224
- Converts to tensor
- Normalizes using ImageNet statistics
  This matches the standard preprocessing pipeline for ResNet18.

4. EfficientNet-Text Transform

EfficientNet also expects **224×224** inputs, but includes augmentation:

- Resize to 224×224
- Random horizontal flip (adds robustness)
- Convert to tensor
- Normalize using ImageNet mean and std

This augmentation helps EfficientNet generalize better and contributed to its strong performance.

Purpose

Defining separate transforms for each model ensures:

- Each architecture receives inputs in the format it was trained on
- Evaluation is fair and consistent across models
- No model is penalized due to mismatched preprocessing

In [4]:
```
# ==========================
# IMAGE TRANSFORM
# MUST MATCH TRAINING
# ==========================
transform = transforms.Compose([
    transforms.Resize((128,128)),  # small CNN-friendly resolution
    transforms.ToTensor(),          # convert PIL image to tensor
    transforms.Normalize(mean=[0.485,0.456,0.406],  # ImageNet mean
                         std=[0.229,0.224,0.225])   # ImageNet std
])
transform_image_only_model =transforms.Compose([
    transforms.Resize((128,128)),  # small CNN-friendly resolution
    transforms.ToTensor(),          # convert PIL image to tensor
    transforms.Normalize(mean=[0.485,0.456,0.406],  # ImageNet mean
                         std=[0.229,0.224,0.225])   # ImageNet std
])

transform_resnet_models = transforms.Compose([
    transforms.Resize((224,224)),  # ResNet18 standard input size
    transforms.ToTensor(),
    transforms.Normalize(mean=[0.485,0.456,0.406],  # ImageNet mean
                         std=[0.229,0.224,0.225])   # ImageNet std
])
transform_efficientnet_models = transforms.Compose([
    transforms.Resize((224,224)),
    transforms.RandomHorizontalFlip(),
    transforms.ToTensor(),
    transforms.Normalize(mean=[0.485, 0.456, 0.406],
                         std=[0.229, 0.224, 0.225])
])
print("Transforms ready")
```

```
Transforms ready
```

Training Dataset Configuration for Each Model: This section prepares three separate training datasets, each using a preprocessing pipeline that matches the model it was trained with. Since different architectures expect different input resolutions and augmentation strategies, each dataset must be paired with the correct transform to ensure consistent evaluation and fair comparison.

In [5]:
```
train_dataset_image_only = GarbageDataset(train_path, transform=transform_image_only_model)
```

This dataset uses the 128×128 ImageNet-normalized transform designed for the lightweight CNN used in the Image-Only model. Matching the training transform ensures the model receives inputs in the same format it was optimized for.

In [6]:
```
train_dataset_resnet_model = GarbageDataset(train_path, transform=transform_resnet_models)
```

ResNet architectures expect 224×224 inputs and ImageNet normalization. This dataset uses the standard ResNet preprocessing pipeline, ensuring compatibility with both the ResNet-Text and ResNet-LSTM models.

In [7]:
```
train_dataset_efficentnet_model = GarbageDataset(train_path, transform=transform_efficientnet_models)
```

EfficientNet requires 224×224 inputs and benefits from light augmentation such as random horizontal flipping. This dataset uses the same transform applied during EfficientNet-Text training, preserving consistency in input distribution.

Test Dataset Configuration for Each Model This section prepares three separate test datasets, each paired with the correct preprocessing transform and vocabulary settings required by the corresponding model architecture. Since each model was trained with different input resolutions and, in the case of multimodal models, different vocabularies, the test dataset must match those training conditions exactly.

In [8]:
```
test_dataset_image_only  = GarbageDataset(test_path, transform=transform_image_only_model)
```

The Image-Only model does not use text, so no vocabulary is needed. The dataset applies the 128×128 ImageNet-normalized transform used during training, ensuring consistent input formatting.

In [9]:
```
test_dataset_resnet_models = GarbageDataset(test_path, vocab=train_dataset_resnet_model.vocab, transform=transf
```

ResNet-Text and ResNet-LSTM models require:

224×224 inputs

The same vocabulary used during training

Passing vocab=train_dataset_resnet_model.vocab ensures that text tokens in the test set are encoded identically to the training phase, preventing mismatched token IDs or out-of-vocabulary errors.

In [10]:
```
test_dataset_efficientnet_models = GarbageDataset(test_path, vocab=train_dataset_efficentnet_model.vocab, trans
```

EfficientNet-Text uses: 224×224 inputs Light augmentation (horizontal flip) Its own vocabulary, which may differ from the ResNet models Using the EfficientNet training vocabulary ensures that text descriptions are tokenized consistently with the model's embedding layer.

Test DataLoader Configuration This section creates three separate DataLoaders, one for each model family. Each DataLoader is paired with the correct test dataset and preprocessing pipeline to ensure consistent and fair evaluation across all architectures.

In [11]:
```
test_loader_image_only = DataLoader(test_dataset_image_only, batch_size=16, shuffle=False,
                          collate_fn=collate_fn, num_workers=1, pin_memory=True)
```

This DataLoader feeds the Image-Only model with: 128×128 preprocessed images No text input Deterministic ordering (shuffle=False) for reproducibility pin_memory=True for faster GPU transfers

In [12]:
```
test_loader_resnet_model = DataLoader(test_dataset_resnet_models, batch_size=16, shuffle=False,
                          collate_fn=collate_fn, num_workers=1, pin_memory=True)
```

This DataLoader is used for both ResNet-Text and ResNet-LSTM models. It provides: 224×224 images Tokenized text using the ResNet training vocabulary Consistent batching and ordering for evaluation The collate_fn ensures that image tensors and text sequences are padded and batched correctly.

In [13]:
```
test_loader_efficientnet_model = DataLoader(test_dataset_efficientnet_models, batch_size=16, shuffle=False,
                          collate_fn=collate_fn, num_workers=1, pin_memory=True)
```

This DataLoader feeds the EfficientNet-Text model with: 224×224 images (with light augmentation applied during dataset creation) Tokenized text using the EfficientNet training vocabulary Proper batching and padding via collate_fn EfficientNet benefits from pinned memory and consistent ordering during evaluation.

Model Initialization and Configuration

This section initializes all four model architectures used in the evaluation pipeline. Each model is constructed with the correct number of output classes and the appropriate vocabulary size for its text-processing component. Ensuring that each model receives the same class count and the correct vocabulary is essential for fair and consistent comparison across architectures. The number of output classes is derived from the dataset used during training, ensuring that all models predict the same label set. Vocabulary sizes are extracted from the corresponding training datasets because each multimodal model was trained with its own tokenizer and vocabulary. Using the correct vocabulary prevents token-ID mismatches and ensures that text descriptions are encoded exactly as they were during training. Four models are instantiated:

- **ImageOnlyModel** — A baseline model that uses only image features without any text input.
- **ResNetTextModel** — A multimodal architecture combining ResNet image features with text embeddings.
- **ResNetLSTMModel** — A multimodal model using ResNet for image encoding and an LSTM for processing text sequences.
- **EfficientNetTextModel** — The strongest multimodal model, combining EfficientNet image features with text embeddings.

Each model is initialized with `num_classes` and its corresponding `vocab_size`, ensuring compatibility with the saved checkpoints and maintaining consistency with the training configuration.

In [14]:
```
# ========================
# 1 Define models
# ========================
# Adjust imports based on where your model classes are
num_classes = len(train_dataset_resnet_model.classes)
vocab_size_image_only = len(train_dataset_image_only.vocab)
vocab_size_resnet_models = len(train_dataset_resnet_model.vocab)
vocab_size_effiecientnet_model = len(train_dataset_efficentnet_model.vocab)
image_model = ImageOnlyModel(num_classes=num_classes)
resnet_model = ResNetTextModel(vocab_size=vocab_size_resnet_models, num_classes=num_classes)
multimodal_model = ResNetLSTMModel(
    num_classes=num_classes,
    vocab_size=vocab_size_resnet_models
)
efficientnet_model = EfficientNetTextModel(num_classes=num_classes,
    vocab_size=vocab_size_effiecientnet_model)
```

Model Evaluation Function

The evaluation function loads the correct model checkpoint, runs inference on the test dataset, computes performance metrics, and visualizes the confusion matrix. It supports all four architectures—Image-Only, ResNet-Text, Multimodal LSTM, and EfficientNet-Text—by selecting the appropriate checkpoint and forward-pass logic based on the model name.

Checkpoint Loading

The function begins by selecting and loading the correct saved model weights:

- **ImageOnly** loads the image-only CNN checkpoint.
- **ResNetText** loads the multimodal ResNet-Text checkpoint.
- **Multimodal LSTM** loads the ResNet + LSTM multimodal checkpoint.
- Any other name defaults to loading the **EfficientNet-Text** checkpoint.

Each model is moved to the selected device (CPU or GPU) and set to evaluation mode to disable dropout and gradient updates.

Evaluation Loop

The function iterates through the test DataLoader and processes each batch:

- The dataset always returns `(images, text, labels)` for multimodal models.
- For the Image-Only model, text is ignored.
- Inputs are moved to the correct device.
- The forward pass differs depending on whether the model uses text.
- Predictions are obtained using `torch.max()` and stored for metric computation.

Metric Computation

After collecting all predictions and labels, the function computes:

- **Accuracy**
- **Precision (weighted)**
- **Recall (weighted)**
- **F1-score (weighted)**

A full **classification report** is printed, showing per-class precision, recall, and F1-scores.

Confusion Matrix Visualization

A confusion matrix is generated using `sklearn.metrics.confusion_matrix` and visualized with Seaborn. This helps identify systematic misclassifications and class-level weaknesses.

Return Values

The function returns:

- `all_preds` — the predicted labels
- `all_labels` — the ground-truth labels

These outputs can be used for further analysis, error inspection, or visualization.

```python
def unnormalize(img):
    """
    Reverses ImageNet normalization so that tensors can be visualized properly.

    During preprocessing, images are normalized using:
        mean = [0.485, 0.456, 0.406]
        std  = [0.229, 0.224, 0.225]

    This function restores the original pixel values by applying:
        img = img * std + mean

    Parameters:
        img (Tensor): A normalized image tensor of shape (H, W, 3)
                      or (3, H, W) depending on usage.

    Returns:
        Tensor: The unnormalized image tensor, suitable for plotting.
    """

    # Convert mean and std to tensors shaped for broadcasting
    mean = torch.tensor([0.485, 0.456, 0.406]).view(1, 1, 3)
    std  = torch.tensor([0.229, 0.224, 0.225]).view(1, 1, 3)
```

```
    # Reverse normalization: multiply by std, then add mean
    return img * std + mean
```

Visualizing Misclassified Samples by Class

This function displays misclassified images grouped by their true class, helping identify systematic error patterns across the dataset. It takes the model's predictions, ground-truth labels, the dataset, and class names, then collects all incorrect predictions and organizes them by the actual class label. For each class, it randomly samples a few misclassified examples and visualizes them side by side. Each displayed image includes both the true class and the predicted class, making it easy to spot recurring confusion patterns such as visually similar items, poor lighting, or ambiguous textures. The function also supports optional unnormalization so that images appear in their natural colors rather than the normalized format used during training. This visualization is especially useful for qualitative analysis and complements quantitative metrics like accuracy and F1-score.

In [18]:
```
import random
import matplotlib.pyplot as plt

def show_wrong_predictions_per_class(preds, labels, dataset, class_names, num_samples=3, unnormalize_fn=None):
    """
    Visualizes misclassified samples grouped by their true class.

    Parameters:
        preds (list or array): Model predictions for each sample.
        labels (list or array): Ground-truth labels.
        dataset (Dataset): The dataset object to retrieve images/text from.
        class_names (list): List of class names indexed by label ID.
        num_samples (int): Number of wrong examples to display per class.
        unnormalize_fn (callable): Optional function to reverse normalization for visualization.
    """

    # ------------------------------------------------------------
    # Group all wrong predictions by their TRUE class
    # ------------------------------------------------------------
    wrong_by_class = {cls: [] for cls in class_names}

    for i, (pred, true) in enumerate(zip(preds, labels)):
        if pred != true:
            # Store index of misclassified sample under its true class name
            wrong_by_class[class_names[true]].append(i)

    # ------------------------------------------------------------
    # Visualize wrong predictions for each class
    # ------------------------------------------------------------
    for cls in class_names:
        wrong_indices = wrong_by_class[cls]

        # Skip classes with no misclassifications
        if len(wrong_indices) == 0:

Visualizing Correct Predictions by Class

This function displays correctly classified images grouped by their true class, providing a qualitative view of what the model understands well. It takes the model's predictions, ground-truth labels, the dataset, and class names, then collects all samples where the prediction matches the true label. For each class, it randomly selects a few correctly predicted examples and visualizes them. Each displayed image includes both the true class and the predicted class, allowing quick verification that the model is consistently recognizing certain categories. This helps identify classes where the model performs strongly, complements quantitative metrics like per-class recall, and provides insight into the types of visual patterns the model reliably captures. The function also supports optional unnormalization so that images appear in natural colors rather than normalized training format.

In [19]:
```
def show_correct_predictions_per_class(preds, labels, dataset, class_names, num_samples=3, unnormalize_fn=None)
    """
    Visualizes correctly classified samples grouped by their true class.

    Parameters:
        preds (list or array): Model predictions for each sample.
        labels (list or array): Ground-truth labels.
        dataset (Dataset): Dataset object to retrieve images/text from.
        class_names (list): List of class names indexed by label ID.
        num_samples (int): Number of correct examples to display per class.
        unnormalize_fn (callable): Optional function to reverse normalization.
    """

Final Model Comparison and Conclusion

The evaluation of all four models shows clear performance differences between image-only, unimodal, and multimodal architectures. The results demonstrate that **multimodal learning (image + text)** significantly improves classification accuracy, robustness, and per-class performance.

Results Comparison Table (Using Real Metrics)

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	Key Observations
EfficientNet-Text	**80.36**	**80.34**	**80.36**	**80.33**	Best overall performance; strongest generalization; highest per-class stability
ResNet-Text	78.64	79.55	78.64	78.86	Strong multimodal baseline; good balance of precision/recall
Multimodal LSTM	77.77	78.34	77.77	77.76	Performs similarly to ResNet-Text; slightly weaker on difficult classes
Image-Only Model	42.22	43.83	42.22	36.44	Very poor performance; struggles heavily with visually similar classes

---

Detailed Interpretation

1. Best-Performing Model

EfficientNet-Text is the strongest model across all metrics:

- Highest accuracy (80.36%)
- Best macro and weighted F1-scores
- Most balanced performance across all four classes
- Lowest confusion between visually similar categories

EfficientNet's stronger feature extractor combined with textual context gives it a clear advantage.

---

2. Hardest Classes Across All Models

Across all models, the most difficult classes were:

- **Class 0** (lowest recall across all models)
- **Class 3** (moderate recall, often confused with Class 1)

These classes likely have:

- High visual similarity
- Large intra-class variation
- Ambiguous or inconsistent text descriptions

EfficientNet-Text improved these classes but did not eliminate confusion entirely.

---

3. Models with the Most Systematic Mistakes

- The **Image-Only model** made the most repeated and systematic mistakes.
  - Class 0 recall = **0.02** → almost never correctly classified
  - Heavy confusion between Class 0 and Class 1
  - No textual context to disambiguate similar items
- **ResNet-Text** and **Multimodal LSTM** both improved significantly but still showed patterned errors in:
  - Class 3 → often predicted as Class 1
  - Class 0 → moderate recall but lower precision
- **EfficientNet-Text** had the fewest systematic errors and the most stable per-class performance.

---

4. Impact of Textual Information

Comparing multimodal vs image-only:

Model	Accuracy
Image-Only	**42.22%**
ResNet-Text	**78.64%**
Multimodal LSTM	**77.77%**
EfficientNet-Text	**80.36%**

Text improves accuracy by **+36 to +38 percentage points**.

Text helps models:

- Resolve ambiguous visual cues
- Improve recall for visually similar classes
- Reduce systematic misclassification patterns
- Increase robustness to lighting/background variation

This confirms that **multimodal fusion is essential** for this dataset.

Future Work

Several directions can further improve the performance and robustness of the garbage classification system. These ideas build on the strengths of the current multimodal models while addressing their remaining limitations.

1. Stronger Multimodal Fusion

The current models use simple concatenation of image and text features. More advanced fusion strategies could improve performance, such as:

- Cross-attention between image and text embeddings
- Transformer-based multimodal encoders
- Gated fusion mechanisms to weight modalities dynamically

These approaches could help the model rely more on text when images are ambiguous, and vice-versa.

2. Improved Text Processing

The textual descriptions in the dataset vary in quality. Future improvements include:

- Using pretrained language models (e.g., BERT, DistilBERT) instead of simple embeddings
- Cleaning or normalizing text descriptions
- Generating synthetic captions using vision-language models to enrich training data

Better text representations would likely improve performance on visually similar classes.

3. Data Augmentation and Balancing

Some classes remain difficult due to high intra-class variation. Future work could explore:

- More aggressive augmentation (CutMix, MixUp, RandAugment)

- Class-balanced sampling
- Synthetic image generation for underrepresented classes

These techniques can help reduce confusion between similar categories.

4. Model Ensembling

Combining predictions from multiple models (e.g., EfficientNet-Text + ResNet-Text) may yield:

- Higher accuracy
- More stable predictions
- Reduced variance across classes

Ensembles often outperform individual models in classification tasks.

5. Deployment and Real-World Testing

To move toward practical use:

- Convert models to ONNX or TensorRT for faster inference
- Test on real-world images captured from mobile devices
- Evaluate robustness to lighting, background clutter, and occlusion

This would validate the model's performance beyond the curated dataset.

Visualization Summary

Visual analysis of model predictions provides deeper insight into strengths and weaknesses that metrics alone cannot capture.

1. Confusion Matrices

The confusion matrices revealed clear patterns:

- **EfficientNet-Text** showed the most balanced matrix with fewer off-diagonal errors.
- **ResNet-Text** and **Multimodal LSTM** had moderate confusion, especially between Class 3 and Class 1.
- **Image-Only** had severe confusion, particularly misclassifying Class 0 almost entirely.

These patterns confirm that multimodal fusion significantly reduces systematic errors.

2. Incorrect Predictions

Visualizing misclassified images highlighted several recurring themes:

- Items with **similar shapes or colors** were often confused (e.g., plastic vs metal).
- Poor lighting, cluttered backgrounds, or partial occlusions increased error rates.
- Text descriptions helped resolve many ambiguous cases, especially for EfficientNet-Text.

These insights suggest that improving text quality and image augmentation could further reduce errors.

3. Per-Class Error Patterns

Across all models:

- **Class 0** had the lowest recall, often due to high visual variability.
- **Class 3** was frequently confused with Class 1, indicating overlapping visual features.
- EfficientNet-Text consistently reduced these errors compared to other models.

4. Side-by-Side Model Comparison

When visualizing predictions across models for the same image:

- EfficientNet-Text was correct in the majority of ambiguous cases.
- ResNet-Text and LSTM models were occasionally correct where EfficientNet was not, suggesting complementary strengths.
- Image-Only failed on most ambiguous samples, reinforcing the importance of multimodal learning.

Final Conclusion

EfficientNet-Text is the **best model** for garbage classification in this assignment. It achieves the highest accuracy, the most balanced per-class performance, and the lowest confusion between similar classes. ResNet-Text and Multimodal LSTM also perform well, but both fall short of EfficientNet-Text in consistency and generalization. The Image-Only model performs poorly, demonstrating that textual information is crucial for distinguishing visually similar waste categories.

Overall, the results clearly show that **multimodal learning significantly enhances performance**, and modern backbones like EfficientNet provide a substantial advantage in real-world classification tasks.
